

Transparent partition of the three-level distribution box

AI Overview

The three-level distribution box in distributed databases represents fragmentation transparency, location transparency, and local mapping transparency, which collectively hide the complexity of data distribution from users.

Overview of Three-Level Distribution Transparency

In a distributed database system, distribution transparency ensures that users and applications can interact with data without needing to know how it is fragmented, where it is stored, or which local database system manages it. The three levels of transparency are:

- **Fragmentation Transparency** This level allows users to query a table as if it were a single, unfragmented entity, even though the table may be split into multiple fragments stored at different sites. Users do not need to know the fragmentation details, which simplifies query formulation and ensures data consistency across fragments.
- **Location Transparency** Location transparency hides the physical location of data fragments. Users can access any fragment as if it were stored locally, without knowing the site name or network address. This enables seamless querying across distributed sites and supports parallel execution of subqueries on different fragments.
